SECTION I

INTRODUCTION

1-1. PURPOSE. Volume IV presents the methodology for evaluating analyses of samples from nonaeronautical equipment. The methodology enables an evaluator to identify wear-metals present in the sample and their probable sources, to judge equipment condition, and to make recommendations, which influence maintenance and operational decisions. Following these recommendations can enhance safety and equipment reliability and contribute to more effective and economic maintenance practices. Test procedures are contained in Volume II.

1-2. Applicability. The provisions of this manual apply to all activities of the Departments of the Army, Navy, and the Air Force participating in the Joint Analysis Program (JOAP) and analyzing nonaeronautical samples. They also apply to the laboratories operating under contract or mutual assistance agreements therewith.

1-3. Manual Change Procedures. Detailed procedures for manual changes are contained in Volume I.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION II

NONAERONAUTICAL EQUIPMENT ANALYTICAL METHODOLOGY

2.1. General.

a. Each moving part in a machine has a normal rate of wear. As machine components wear, microscopic metallic wear particles are generated. Some microscopic particles are small enough to pass through a filter and remain suspended in the lubricating oil. When a machine is operating normally and operated under normal conditions, the concentration of these wear particles will be fairly consistent at the end of each oil change period. However, differences in load and working environment will affect the rate of wear of the machine components, as will various internal oil system problems and component friction changes. When abnormal wear takes place in the equipment, the concentration of one or more elements will increase significantly. Therefore, the concentration of wear particles will not always be the same and the evaluator must interpret the results of oil sample analysis to determine the reason for the changes detected and the possible effects of these changes on the equipment.

b. The JOAP nonaeronautical analytical methodology encompasses the interpretation of used oil sample analysis results, assessment of equipment and oil condition based on analysis results, diagnosis of the probable sources of wear-metals and contaminants, and the issuance of accurate and effective equipment maintenance and operational recommendations to the operating activity. The methodology uses wear-metal evaluation criteria tables by type equipment and individual equipment diagrams (Appendix B and D) as well as subjective evaluation of a series of laboratory test.

(1) The wear-metal evaluation criteria tables provide the wear-metal range and trend values which relate the oil sample wear-metal concentration to the expected condition of the equipment or oil condition. These tables also contain supplemental technical information to assist the evaluator in identifying the most probable sources of wear-metal. For some equipment, the criteria have not been determined but will be added when available. Data provided in these tables are intended for use as guidelines by evaluators, not as strict go/no-go criteria. The guidelines were statistically derived using analysis of samples from operating equipment from various geography locations. Absolute values that will indicate specific impending component failures may actually be somewhat above or below the concentration levels shown. Therefore, the evaluator must apply subjective judgement, experience, and knowledge of the particular component from which a sample is taken to determine evaluation recommendations.

(2) The individual equipment diagrams present wear-metals source information keyed to location by the use of equipment cutaway schematics. The cutaway or cross sectional figures for the equipment provide detailed breakout information of metallic elements present in the equipment. In some instances, the figures identify elements that will not be detected by the spectrometer. These elements are shown for evaluator information only, with the possibility that they may be detected by other laboratory methods. In cases where the major element for a component is known, it is indicated by being shown first and underscored. Generally, the combinations of elements shown are listed in descending order of the amounts present in the components.

NOTE

The Engine/Transmission/Equipment Cross Index listing in Appendix B includes a cross index for nonaeronautical equipment items. The end items shown in the appendix for a particular engine or transmission may not be the only equipment which utilize that particular engine/transmission.

2.2. Wear-Metal Sources.

a. Internal combustion engines are subject to contamination from external sources such as sand and dirt, as well as internal sources, such as blow-by combustion contaminants and wear-metals from various oil-wetted moving parts, which are deposited in the oil system in varying degrees, depending upon the equipment condition.

b. Transmissions are difficult to evaluate and may be relatively easily contaminated with dirt, sand, and water. Transmissions may reveal high increases in debris (both metals and nonmetals) without detrimental wear of the oil-wetted working components. Therefore, the evaluator should be familiar with the transmissions being evaluated and also with any factors that might cause extreme or sudden increases in transmission oil contamination.

c. The specific metals that may normally be found in diesel engines and transmissions of nonaeronautical equipment used by the military services are discussed below:

(1) Iron (Fe). Iron is one of the most common wear-metals found in oil samples. Iron may be generated from the wear of cylinder walls, shafts, gears, rolling element bearings, splines, and numerous other engine or transmission parts. Iron may also be the result of machining chips or debris left in the equipment oil system during manufacture or overhaul. Iron may also be present as a result of rust in some equipment.

(2) Silver (Ag). Silver is used as plating on some oil seals and bushings and may also be found in small amounts in some sleeve bushings.

(3) Aluminum (Al). Aluminum may be found in the oil systems of engines and transmissions because of the wear of pistons, washers, shims, some oil pumps, torque converters, housings or cases, etc. It may also be the result of machining chips or debris left in the equipment oil system during manufacture or overhaul.

(4) Chromium (Cr). Chromium in the oil system may result from the wear of numerous oil-wetted parts that are alloyed or plated with chromium. The most common occurrence will probably result from wear of chromium plated piston rings.

(5) Copper (Cu). Copper is found in connecting rod and main bearings, many bushings, thrust washers and piston pin bearings.; Also, many transmission and brake plates contain sintered bronze, which is very high in copper content.

(6) Silicon (Si). Although not a metallic element, silicon is commonly present in many oil systems and may be detected by spectrometric testing. The main source of silicon in engines (silica) is from external sources through the air induction system, which may admit significant amounts of dirt or sand if not maintained properly. Silicon may also be introduced in the form of dirt or sand during maintenance if proper maintenance practices are not observed. Aluminum and cast iron parts used in both engines and transmissions have significant amount of silicon. Some seals and gaskets, as well as antifoaming agents in oils, also contain silicon and/or silicone.

(7) Tin (Sn). Tin is used to plate some engine pistons and may also be present in connecting rod and main bearings, many bushings, thrust washers and piston pin bearings.

(8) Nickel (Ni). Nickel is used for plating and as an alloying element in many oil-wetted components. Some cast irons and stainless steels contain significant amounts of nickel.

(9) Lead (Pb). Lead is used for plating and may be found in significant amounts in connecting rod and main bearings, bushings, thrust washers and piston pin bearings. Lead may also be found in transmission clutch and brake friction plates.

(10) Molybdenum (Mo). Molybdenum is used as an alloying element in many oil-wetted engine and transmission components. Molybdenum is also used as a coating on the top, second, and third compression rings in the Continental AVDS 1790 engines and on the top ring of the Caterpillar 3208 engines.

(11) Magnesium (Mg). Magnesium is used as an alloying element in some oil-wetted components but is not employed extensively for nonaeronautical vehicles where weight is a less significant factor.

2-3. Lubricant and Hydraulic Fluid Information.

a. Specifications. Military specifications for lubricants and hydraulic fluids are frequently published in a format which includes sections describing the intended use of the oil/fluid, referenced documents, lubricant/fluid property requirements, level of performance, quality assurance provisions, test procedures for determination of properties, packaging and marking instructions, and qualification procedures. A specific military agency is responsible for the qualification of oils/fluids to each specification. The agency determines, from in-house or commercial laboratory evaluation data that products submitted for qualification meet all specification requirements. Periodically, an updated submitted for qualification meet all specification requirements. Periodically, an updated qualified products lists (QUPL) is published for each specification giving the government designation (if any) for the lubricant, the manufacturer's designation for the lubricant/fluid, a test or qualification reference number/fluid, and the manufacturer's name and address.

b. Military and NATO Symbols. Lubricating engine and gear oils and hydraulic fluids are generally identified by military symbols and, in some instances, NATO Code Number designations. To provide a ready reference for specification products, table 2-1 lists military lubricant and hydraulic fluid specifications with their respective grade and military and NATO designations.

c. Within the confines of this discussion, a lubricant serves the following functions.

(1) Provides a film to reduce friction between rolling and sliding hardware components, i.e., roller and ball bearings and races, sleeve bearings and shaft surfaces, piston rings and cylinder liners, etc. Adequate lubricant film strength under extreme pressures and temperatures assures minimum metal-to-metal scuffing, scoring, and reduced overall wear.

(2) Provides a medium to transfer heat caused by friction from critical working surfaces.

(3) Acts as a flushing liquid to carry away wear particles and other foreign material.

(4) Contains additives which:

(a) Suspend combustion blow-by products and debris in the oil.

(b) Provide a sealing medium in piston engines.

(c) Maintain the cleanliness of critical component surfaces.

(d) Chemically react with power-system produced contaminants to neutralize their adverse effects.

d. Additives.

(1) Additives are normally classified as detergents, dispresants, oxidation inhibitors, corrosion inhibitors, anti-wear agents, pour point depressants, or anti-foam agents.

NOTE

Commercially available automotive oil additives should not be used as supplements for military specification oils since the additives may be incompatible and may result in a partial or complete loss of vital oil characteristics. Problems such as increased pour points, foaming tendencies, bearing wear, engine corrosion, and piston ring deposits have been identified with additive misapplications, which have resulted in equipment malfunction and damage.

(2) Each type of lubricant is formulated to meet a specific function and set of operating conditions. The quality of the lubricant basestock and the intended application will dictate the need for a particular additive type. Table 2-2 lists the various types of additives, which may be used, corresponding chemical compound types and those chemical elements detectable by spectrometric analysis. Since numerous chemical compounds may be used within each additive class, only general descriptions of additive compositions can be given. In many cases, determination of the presence or absence of a specific additive can only be made through chemical analysis. This is especially true if the additive is an organic compound and contains no unique chemical elements other than the more common elements of carbon, hydrogen, oxygen, and nitrogen.

NOTE

Lubricant manufactures frequently use additives, which may be misinterpreted as wear-metals during spectrometric analysis. An example of this is the use of copper as and anti-oxidant.

TABLE 2-2. LUBRICANT ADDITIVES

<u>Additive Type</u>	<u>Chemical Type</u>	<u>Elements Detectable By Spectrometric Analysis</u>
Antioxidant	Organic Metallo-organic	None Zn, Cu
Detergent	Metallo-organic	B, Ba, Mg, Na
Dispersant	Organic	None
Load-carrying	Organic Metallo-organic	None Zn
Corrosion inhibitor	Organic Metallo-organic	None Zn
VI improver	Organic	None
Anti-foam	Organic-silicone	Si
Pour point depressant	Organic	None

2-4. Lubricant Degradation.

a. Causes. Three basic factors control lubricant degradation: service time, operating temperature, and contamination. Time and temperature are directly related. The useful life of a lubricant is extended when equipment is operated at moderate operating temperatures and it is reduced when equipment is operated at severe operating temperatures such as sustained engine operation at high loads or continuous operation with high-sulfur fuel.

b. Effects. Breakdown of a formulated lubricant may be associated with oxidative deterioration of the basestock or depletion or modification of a particular additive. Oxidative deterioration results in the formation of acids, which promote corrosion and organic products. These products increase the viscosity of the oil. The effect of a significant increase in viscosity is a reduction in the pumpability of the lubricant and the amount of lubricant flow through delivery jets and ports. This reduces the lubricant ability to reduce friction, transfer heat, flush contaminants, and maintain component cleanliness. Products resulting from oxidative deterioration may also promote the formation of deposits, which can interfere with the operation of mechanical components and plug oil filters and jets. Additive depletion results in the reduction of loss of the lubricant property which the additive was intended to provide such as detergency, dispersancy, and lubricating ability.

c. Contamination. Lubricant contamination may occur as a consequence of faulty maintenance practices, poor handling techniques with new replacement oil, system-ingested contaminants, or system-generated contaminants.

(1) System Ingested. In internal combustion engines, the main ingested contamination is dirt and/or sand, which causes abrasive wear of mechanical components. The introduction of such contamination is usually caused by a malfunction in the engine air induction system (damaged air filter, air hoses, etc.). This type of contamination will normally be detected as high silicon during spectrometric analysis of system oil samples.

(2) System Generated. Several types of system-generated contaminants may occur. Examples include antifreeze fluid, water, unburned fuel, and various products of combustion (blow-by products), which enter the lubricant crankcase through the piston ring area. Wear-metals may also be considered a special type of system-generated contaminant. The presence (or absence) of wear-metals is an indication of the integrity and condition of the oil wetted mechanical system. If wear particles of appreciable size are generated, damage to mating surfaces such as gears and bearings may occur.

(3) Contaminant Types. Table 2-3 lists the various types of lubricant contaminants, which may be found, the significance of the contamination and the corresponding analytical methods for contaminant detection.

2-5. Equipment Analysis Requirements.

a. Engines. As a minimum, all Army and Marine engine samples shall be evaluated by four screening test procedures: spectrometric analysis, viscosity, blotter spot test and test for water. If the results obtained for any screening test are outside the evaluation guidelines, the laboratory evaluator shall consider the nature and degree of the failing result and schedule additional testing as required. See table 2-4 for testing requirements. See appendix D for Navy Ship requirements. A recommendation for maintenance action should not be made until a resample has been requested to verify the suspected situation.

(1) Spectrometric values which exceed guidelines listed on applicable criteria tables should be evaluated to determine whether a critical situation exists and the appropriate laboratory recommendation should be assigned. For example, a verification sample that confirms excessive wear-metal concentrations is considered a critical situation and warrants a recommendation for maintenance action. But an increasing wear trend on a routine sample is not considered a critical situation; it warrants a recommendation for resampling.

TABLE 2-3. LUBRICANT CONTAMINANTS

<u>Contaminant Type</u>	<u>Significance</u>	<u>Analytical method</u>
Wear-metals	System wear	Spectrometer
Coolant	Emulsifies oil, impairs lubrication, destroys dispersant additives	Crackle test; blotter spot; spectro for Na, B
Free Water	Corrosion, emulsifies Oil, impairs lubrication	Crackle test; blotter spot; spectro for Na with Marine equipment, visual inspection
Fuel	Lowers oil viscosity	Viscosity; Alkalinity Test
Dirt, sand	Causes abrasive wear	Spectro for Si, Al; blotter spot; visual inspection
Blow-by products, Soot	Increases viscosity, forms sludge	Viscosity; blotter spot
Reactive compounds	Corrosion, viscosity increase	Viscosity; Alkalinity Test
Rust	Internal Corrosion	Spectro for Fe

NOTE

A request for a sample of the new oil from stock is desirable whenever an increase in an element is suspected to be the result of additives from an oil addition.

Spectrometric results should also be evaluated for foreign contamination such as ingested dirt, evidenced by high silicon or aluminum, or engine coolant leakage, evidence by increases in sodium and boron. Additive levels may be shown by spectrometric data for elements such as zinc, boron, magnesium, or sodium.

(2) Viscosity guidelines for MIL-L-2104, the oil most commonly used in the Nametre viscometer. Viscosity results below minimum guidelines indicate the sample should be tested for fuel dilution. Viscosity results above maximum guidelines indicate the sample should be tested for total contaminants by blotter test and for water by crackle or Karl Fischer. Alkalinity should also be checked because low alkalinity means acids are being produced which are depleting the alkaline additives in the oil. These acids can form products which increase the viscosity. Viscosities for oils other than MIL-L-2104 should be evaluated by comparing the viscosity of the used oil sample to the viscosity of a sample of the new oil.

**TABLE 2-4. NONAERONAUTICAL EQUIPMENT LUBRICANT SAMPLE
 ANALYSIS REQUIREMENT GUIDE**

The sequence of the following tests is provided as a guide, not as mandatory requirements for all services.

I. ENGINES

A. Spectrometric

1. Pass - Go to I.B.
2. Fail - See wear-metal guidelines for specific equipment
 - a. Critical - Resample to verify
 - (1) Wear-Metals - abnormal or high range
 - (2) Oil contamination by dirt or dust - Si increase
 - b. Noncritical - Resample to verify, then change oil
 - (1) Oil contamination by dirt or dust - Si increase
 - (2) Additive depletion - Zn, Mg, or Cu decrease
 - (3) Coolant problem - B or Na increase by 20 PPM or more

B. Viscosity

1. Pass - Go to I.C.
2. Fail - See viscosity guidelines
 - a. Low - Fuel dilution or wrong oil. Verify by flashpoint test and change oil.
 If repeat problem, make maintenance recommendation for fuel dilution.
 - b. High - Soot, sludge, water or wrong oil. Verify by blotter and water tests and change oil.

C. Blotter

1. Pass - Go to I.D. or I.E.
2. Fail - See blotter test instructions in Vol II, para 4-4.b.
 - a. Contaminated oil - Soot or water is present. Verify by water (crackle or KF) test and change oil
 - b. Additive depletion - Spot has poor dispersancy. Verify by spectrometric Analysis (large decrease in Zn, Mg, or Cu) and change oil.

D. Crackle Test for Water

1. Pass - Go to I.E. if quantitative degree of water content required (optional).
2. Fail - See crackle test instructions in Vol II, para 4-4.d.(1).
 - a. Free water - Change oil.
 - b. Coolant leak - Verify by spectrometric (B or Na increase by 20 PPM or more) and change oil.
 - c. Dissolved water - Verify by KF test and consult guidelines.

E. Karl Fischer Test for Water

1. Pass
2. Fail - See guidelines, Vol II, para 4-4.d. (2).

F. Fourier Transform Infrared (FT-IR) Spectrometric Analysis Results

1. Pass
2. Fail - See FT-IR method number guidelines and analysis test warnings.
 - a. Contaminated oil - Soot or water present.
 - b. Water exceeds guidelines - change oil and service or replace filter.
 - c. Fuel or coolant exceeds guidelines recommending corrective action. If fault is corrected, then perform oil change and service or replace filter.
 - d. Additive depletion or lubricant degradation change oil and service or replace filter.

**TABLE 2-4. NONAERONAUTICAL EQUIPMENT LUBRICANT SAMPLE
ANALYSIS REQUIREMENT GUIDE (Cont)**

II. TRANSMISSIONS

- A. Spectrometric
 - 1. Pass - Go to II.B.
 - 2. Fail - See wear-metal guidelines for specific equipment
 - a. Critical - Resample to verify.
 - (1) Wear-metals - abnormal to high range
 - (2) Oil contamination by dirt or dust - Si increase
 - b. Noncritical - Resample to verify, then change oil.
 - (1) Oil contamination by dirt or dust - Si increase
 - (2) Additive depletion - Zn, Mg, or Cu decrease
 - (3) Water or moisture condensation - Na increase
- B. Viscosity
 - 1. Pass - Go to II.C.
 - 2. Fail - See viscosity guidelines
 - a. Low - Wrong oil, change oil.
 - b. High - Sludge, water or wrong oil. Verify by water test and change oil.
- C. Water Test - Crackle or Karl Fischer
 - 1. Pass
 - 2. Fail - See guidelines, Vol II, para 4-4.d.
- D. Fourier Transform Infrared (FT-IR) Spectrometric Analysis Results
 - 1. Pass
 - 2. Fail - water, oxidation, Ethylene Glycol, Antiwear Region 1, Antiwear Region 2 and Water Readings. Change oil and service or replace filter.

III. HYDRAULIC SYSTEMS

The following tests are approved methods of testing hydraulic fluid condition and may be directed by services as required. These tests may be performed singly or in combination as required. (Army laboratories shall use spectrometric, viscosity, and water testing as a minimum.)

- A. Spectrometric
 - B. Viscosity
 - C. Water testing, Crackle or Karl Fischer Method
 - D. Electronic Particulate Count
 - E. Colorimetric Patch Testing
 - F. Fourier Transform Infrared (FT-IR) Spectrometric Analysis Results
 - 1. Pass
 - 2. Fail - Change oil and service or replace filter.
-

(3) Blotter spot test results reflect the presence or absence of total contaminants, dispersancy additives, and coolant in the oil. Evidence of solids and coolant contamination can be confirmed by reviewing spectrometric results for silicon (for dirt) and sodium and boron (for coolant). The presence of either solids or coolant contamination or the absence of dispersant additives warrants a recommendation to change oil.

(4) Crackle tests result indicate the presence or absence of water. If the test is positive, the blotter spot test should be reviewed for dispersancy because the presence of either free water or coolant will reduce the dispersancy. Review of spectrometric data described above will indicate if the positive test result is caused by coolant.

(5) FT-IR spectrometer tests transmission servicing oils for additive depletion and the presence of contaminants such as soot, fuel, water, coolant (Ethylene Glycol), oxidation, oil additives, or incorrect oil addition. The presence of contaminants or additive depletion warrants a lab recommendation to change oil and service or replace the component filter. If the presence of fuel or coolant is confirmed by a resample, then the AOAP laboratory will issue a DA Form 3254-R, Oil Analysis Recommendation and Feedback, for corrective action.

b. Transmissions. Transmission samples should be evaluated by the screening tests of spectrometric analysis, viscosity, and water determination.

(1) Spectrometric results that exceed criteria shall be evaluated by the screening tests of spectrometric analysis, viscosity, and water determination.

(2) Viscosity values which fail guidelines, either high or low, shall be cause for a laboratory recommendation to change oil.

(3) A crackle test indication of water in the oil shall be cause for a laboratory recommendation to change oil.

(4) FT-IR spectrometer test for presence of contaminants or absence and additives in components servicing oil the following applies. When established guidelines are exceeded, the recommendation will be to change oil and service/replace filter.

c. Hydraulic system. Samples shall be evaluated by spectrometric analysis viscosity, water testing, electronic particulate count, or colorimetric patch testing. (Army samples shall have spectrometric, viscosity, water, and FT-IR testing as a minimum.) Laboratory recommendations for hydraulic systems shall be limited to normal or to change fluid.

2-6. Evaluation Procedure. The following procedure shall be used when evaluating sample results:

a. Determine the range for each critical wear-metal concentration in the sample result from the appropriate equipment wear-metal evaluation criteria table in Appendix B.

Wear-metals considered significant, and for which oil analysis monitoring is required for the particular equipment, are those for which numerical criteria are provided in the applicable equipment criteria table.

b. Review the technical information section included on each criteria table for additional information to be used in the evaluation process.

c. Compare the wear-metal concentration levels of the current sample with the levels of the previous sample to determine whether changes are occurring which indicate developing or impending equipment problems. Analysis readings will normally vary between samples and are generally related to equipment operating time since oil change.

GRADE 15W40	56	117	69	144

d. Determine the wear-metal trend between the last sample and the current sample and compare with the trend limit listed in the criteria table. Most abnormal trends are usually readily apparent. The trends in the table are based on the wear-metal between samples will not be exactly the specified hours; therefore, a conversion must be made for approximate trend value comparison purposes. A trend comparison can be made by dividing the wear-metal increases between samples by the operating hours between samples and then multiplying the results by 10. Trend values for the specified sample intervals are calculated as follows:

$$\frac{A-B}{C-D} \times 10 = \text{trend value for 10 hours}$$

A = PPM this sample
 B = PPM last sample
 C = operating hours this sample
 D = operating hours last sample

NOTE

The formula shown above for calculating trends is a quick way to determine the trend values. However, trend values calculated using this formula for samples taken very frequently may be much less accurate or reliable than trend values calculated for samples taken less frequently. This possibility of error is caused by the spectrometer allowable tolerances and also by the possibility of a variance in the rate of wear-metal production over a period of time. The calculated trend values will be helpful information for the evaluation process, but if samples taken more frequently than at 10 hour intervals are being evaluated, the calculated trend values are not considered accurate for use as equipment acceptable/not acceptable criteria.

e. Wear-metal concentrations exceeding the guidelines but with normal trends may, in some cases, be acceptable, although samples may be required more frequently to minimize the possibility of missing an impending failure.

f. Trend values included in the evaluation criteria tables, are, as previously stated, intended as guidelines for the evaluator, since there are many other factors that must be evaluated to determine actual equipment condition and whether subsequent laboratory recommendations to the customer are required. Generally speaking, trends encountered will fall into one of the following categories:

(1) Level (little or no change): considered normal.

(2) Slightly to moderately increasing or decreasing within trend limits: Usually indicative of problems. A sudden increase may indicate the start of an equipment problem, while a sudden decrease may indicate defective sampling procedures, oil addition/change without documentation, or sample identification problems. Investigation for causes or requests for verification samples and/or decreased sampling interval may be appropriate.

(3) Sharply increasing or decreasing within trend limits: Usually indicative of problems. A sudden increase may indicate the start of an equipment problem, while a sudden decrease may indicate defective sampling procedures, oil addition/change without documentation, or sample identification problems. Investigation for causes or requests for verification samples and/or decreased sampling interval may be appropriate.

(4) Erratic increases and decreases of trend level: This usually indicates a problem in sampling procedure, oil addition or change without documentation, sample identification, etc. This should trigger a request to review activity sampling procedures and submit a verification sample.

(5) Increases exceeding trend limits: Generally indicative of equipment problems. Consult comment sections and equipment history. This will normally result in resample request and/or a maintenance action recommendation.

NOTE

The above categories are subjective since no definitive increase/decrease point value within the trend limits may be arbitrarily assigned. Severity of increase or decreases must be determined by each evaluator after considering all factors involved. The above listing is not considered complete but is provided to show that trend variances, while still within limits, should be monitored to detect impending problems prior to development, whether action recommendations to operating activities are required or not.

g. Determine the appropriate recommendation to be made to the operating activity. Laboratory recommendation codes applicable to nonaeronautical equipment are contained in Appendix A. The majority of sample results will be normal, with the appropriate recommendation Code A. In most cases, this recommendation may be determined without extensive reference to the tables or charts. However, applicable tables and charts for the equipment being monitored should be consulted for any special guidance information.

h. If a recommendation for maintenance action is indicated, the comments sections and equipment diagrams should be reviewed. These may provide additional maintenance information concerning likely problem areas that may warrant inclusion in the laboratory recommendation/maintenance advisory notification to the operating activity.

i. The above procedure can serve as a step-by-step operational guide for evaluator personnel with limited experience, while retaining considerable flexibility for use by an experienced evaluator who can readily take into account the many factors which influence evaluations and recommendations. The judgement of the evaluator is an important part of the evaluation process. Judgement and experience shall not be subordinated by numerical data when reasonable doubt exists in the validity of the recommendation indicated by the numerical data.

APPENDIX A

LABORATORY RECOMMENDATION CODES, NONAERONAUTICAL EQUIPMENT

<u>CODE</u>	<u>GENERAL LAB RECOMMENDATIONS</u>
A	Sample results normal; continue routine sampling.
X	Analysis results supplied to customer; no recommendation required.
Z	Previous recommendation still applies.
<u>CODE</u>	<u>INSPECTION RECOMMENDATIONS (Requires Feedback)</u>
H**	Inspect unit and advise lab of finding. Abnormal wear indicated by (PPM) (element). Resample after (maintenance/** hours/etc.).
K**	Impending failure, critical wear indicates by (element). Inspect unit and advise lab of findings. Resample after (maintenance/** hours/etc.).
L**	Inspect brake and clutch plate adjustments, change oil service filters, resample after *** hours of operation.
M**	Perform engine coast-down check. If engine fails test, examine for discrepancy and advise lab of results; otherwise, resample after *** hours of operation.
U**	Cooling system leak indicated by (Mg/Cr/Na/B). Inspect unit and advise lab of findings. Resample after (maintenance/** hours/etc.).
<u>CODE</u>	<u>OIL CHANGE RECOMMENDATIONS (Requires Resample)</u>
D	Change oil and service filters. Resample after *** hours of operation.
<u>CODE</u>	<u>LAB REQUESTED RESAMPLES (Requires Resample)</u>
B*	Resample as soon as possible; do not change oil.
C*	Resample after *** hours.
F*	Do not change oil. Submit sample after ground or test run. Do not operate until after receipt of laboratory result or advice.
G*	Contamination suspected, do not change oil, resample unit and submit sample from new oil servicing this unit
I*	Stop purification, resample each engine after 4 hours of operation.
N*	Unit 'wear-in' indicated; resample in accordance with break-in schedule or after *** hours.
P*	Do not operate; do not change oil; submit resample as soon as possible.
Q	Normal PPM was obtained from test cell run after complete P.E. where oil lubricated parts were changed/removed/replaced. Monitor engine closely after installation to ensure a normal trend before release to routine sampling.

NOTES:

- *Resample (red cap) required
 **Maintenance feedback required; advise laboratory of findings
 ***Laboratory will specify time limit

STANDARD LAB RECOMMENDATION CODES
PHYSICAL TEST RECOMMENDATIONS
(Not for Air Force Use)

<u>CODE</u>	<u>GENERAL LAB RECOMMENDATIONS</u>
AA	Oil condition normal, continue routine sampling.
DN	Do not operate.
ER	Evaluate and repair component.
TS	Check oil type and source.
XX	Analysis results supplied to customer; no recommendation required.
ZZ	Previous recommendation still applies.

<u>CODE</u>	<u>OIL CONDITION STATEMENTS</u>
FD	Fuel dilution.
NN	Neutralization or acid number.
PC	Particle count excessive.
PN	Precipitation number.
SA	Solid or abrasive material.
VS	Viscosity (high/low/change).
WA	Water.

<u>CODE</u>	<u>OIL CHANGE RECOMMENDATIONS</u>
CS	Change oil and service filter.
CP	Purify, renovate or change oil and service filters.

<u>CODE</u>	<u>LAB REQUESTED SAMPLES (Requires Resample)</u>
RB*	Resample as soon as possible.
RC*	Resample after *** hours.
RH*	Submit hot sample.
RI*	Resample; insufficient amount of sample received.
RS*	Submit sample of new oil servicing this unit.

<u>CODE</u>	<u>INSPECTION RECOMMENDATIONS</u> (Requires Feedback)
IA**	Inspect and repair air induction system.
IC**	Inspect and repair cooling system.
IF**	Inspect and repair fuel system; change/service filters oil.
IW**	Inspect for source of water.

NOTES:

*Resample (red cap) required

**Maintenance feedback required; advise laboratory of findings

***Laboratory will specify time limit

COMPONENT: HMMWV 6.2 Liter Engine Upper Wear Metal Limits

These interim wear metal guidelines are based on the manufacturer's used lubrication oil chemical analysis. The Oil Analysis Standard Interservice System (OASIS) software will be modified to reflect actual wear metal parameters.

Wear Metal/ Coolant Elements		Limits (PPM)	Footnotes
Aluminum	(Al)	50	-
Boron	(B)	20	A,B
Chromium	(Cr)	45	-
Copper	(Cu)	400 (150)	A,B,D,E
Iron	(Fe)	500	A
Lead	(Pb)	115	A
Molybdenum	(Mo)	40	A,B
Silicon	(Si)	90	A,B,C
Sodium	(Na)	50	A,B
Tin	(Sn)	90	-

- A. Values allowed over the component lubrication oils' baseline.
- B. The elements may be present in servicing lubrication oil or coolant additive packages.
- C. This value can be higher on a new engine or engine recently serviced due to silicone form-in-place gaskets being utilized.
- D. Engine(s) used in application where extended idling is required may incur copper readings levels of 600 PPM or higher.
- E. Lower value readings for 1985 year model engines because of revised rocker arm design.

TECHNICAL INFORMATION

A faulty air induction system is normally the major source of silicon in engine oil. Antifoaming agents in engine oil normally contain silicon which will give 3 to 7 PPM in new oil. Silicone coatings may also be used in oil-wetted engine parts. Aluminum and cast iron parts in the engine can have significant amounts of silicon in their composition.

Molybdenum (Mo) levels can be employed to determine the condition of the top (fire) ring. Molybdenum may be present as a dry lubricant or as an additive in some greases, requiring evaluator interpretation.

The engine is liquid-cooled; therefore, ethylene glycol may be present in the engine oil, indicating coolant contamination.

Lead (Pb) is normally generated at relatively high levels during the break-in period of the engine, and then remains fairly constant except for heavy loading, marginal lubrication, or excessive dirt. Increased lead can be the first symptom of bearing distress.

TECHNICAL INFORMATION

A faulty air induction system is normally the major source of silicon in engine oil. Antifoaming agents in engine oil normally contain silicone in engine oil. Antifoaming agents in engine oil normally contain silicone which will give 3 to 7 PPM in new oil. Silicone coatings may also be used in oil-wetted engine parts. Aluminum and cast iron parts in the engine can have significant amounts of silicon in their composition.

If the engine is in operation only occasionally, it may show a significant increase in iron (Fe) wear particles during operation caused by rust of components. Operation during cold and warm periods of the year makes a difference in the concentration of wear particles. When it is cold, the copper values become higher due to an increase of water in the oil caused by condensation. In cold weather there may also be an increase of iron, chromium, lead, and aluminum wear particles caused by increased wear from starting the engine.

The engine is liquid-cooled; therefore, ethylene glycol may be present in the engine oil, indicating coolant contamination.

Lead (Pb) is normally generated at relatively high levels during the break-in period of the engine, and then remains fairly constant except for heavy loading, marginal lubrication, or excessive dirt. Increased lead can be the first symptom of bearing distress.

Abnormal Trend (PPM Increase in 10 hrs)	37	3	16	4	17	22	4	3	11	5	

TECHNICAL INFORMATION

The AVDS 1790-2A engines in the field are being modified to AVDS 1790-2D. AVDS-1790-2C/2D/2/DR engines are classified as Reliability Improvement Selected Equipment (RISE) versions of the engine. The RISE engines retain 10 gallons less residual oil after oil drain than the unmodified engines.

A faulty air induction system is the major source of silicon in engine oil. Silicone coatings may also be used in oil-wetted engine parts. Aluminum and cast iron parts in the engine can have significant amounts (up to 13.5%) of silicon in their composition.

When the rear main seal in an AVDS 1790 engine attached to a CD 850-6A transmission wears excessively or ceases to function properly, there will be cross-contamination of the engine and transmission lubricants. This, in general, will be indicated by increasing or high copper (Cu) and lead (Pb) in the engine oil samples and, simultaneously, increasing or high molybdenum (Mo) in the transmission oil samples.

The engine is air-cooled; therefore, no liquid coolant contamination problems should be experienced.

Aluminum and iron particles from both wear and machining are commonly found in the oil pan.

Aluminum-Silicon
(Al-Si)

Piston wear or piston and cylinder wall wear. Could also be derived from machining chips left in engine.

Iron
(Fe)

Wear of cylinder walls. Wear of numerous other engines parts. Also from machining chips left in engine.

Chromium
(Cr)

Oil control rings are surfaced plated with chromium.

Molybdenum (Mo)	Face of the compression rings are surface plated with molybdenum.
Lead-Tin-Copper (Pb-Sn-Cu)	Crankshaft bearings, both connecting rods, and mains
Iron-Chromium-Nickel (Fe-Cr-Ni)	Oil ring expander spring or fan drive clutch ball
Silver (Ag)	Trace metals in rocker arm roller sleeve bearings

TECHNICAL INFORMATION

The AVDS 1790-8CR is equipped with a power take-off driveshaft employed to power the HH88A2 Hercules' vehicle hydraulic system.

A faulty air induction system is one of the major sources of silicon (Si) in engine oil. Silicone coatings may also be used in oil-wetted engine parts. Aluminum and cast iron parts in the engine can have significant amounts of silicon in their composition.

The cylinder walls are impregnated with a ceramic material consisting of chromium (Cr), magnesium (Mg) and silicon (Si). Significant increases in Cr, Mg, or Si wear material particles during operation may be an early symptom of cylinder wall distress.

When the rear main seal in an AVDS 1790-8CR engine (attached to the XT1410-5A transmission) wears excessively or ceases to function properly, there will be cross-contamination of the engine and transmission lubricants. In general, this will be indicated by increasing or high copper (Cu) and lead (Pb) in the wear metal analysis readings of the engine oil samples and, simultaneously, increasing or high molybdenum (Mo) in the wear metal analysis readings of the transmission oil samples.

The AVDS 1790-8CR engine is air-cooled; therefore, evidence of ethylene glycol or other liquid coolants should not be found in oil sample analysis data.

Aluminum and iron particles from both wear and machining are commonly found in the oil pan.

Operation in cold and warm ambient environment conditions can affect the concentration of wear particles in oil sample analysis data. During cold ambient operations, Cu readings may increase due to increased water contamination from condensation. Additionally, cold ambient engine starting wear may increase for Fe, Cr, Pb and Al wear particle concentrations.

TECHNICAL INFORMATION

A faulty air induction system is normally the major source of silicon in engine oil. Antifoaming agents in engine oil normally contain silicone which will give 3 to 7 PPM in new oil. Silicone coatings may also be used in oil-wetted engine parts. Aluminum and cast iron parts in the engine can have significant amounts of silicone in their composition.

Piston rings and cylinder liners normally shown the most significant wear during operation.

The engine is liquid-cooled; therefore, ethylene glycol present in the engine oil would indicate a leak in the coolant system.

Aluminum-Silicon
(Al-Si)

Piston wear or piston and cylinder wall wear.

Chromium
(Cr)

Oil control rings and first compression ring are chromium plated.

Chromium-Iron
(Cr-Fe)

Ring and Cylinder liner wear.

Iron
(Fe)

Wear of cylinder walls. Wear of numerous other engine parts. Also from machining chips left in the engine.

TECHNICAL INFORMATION

A faulty air induction system is normally a significant source of silicon in engine oil. Antifoaming agents in engine normally contain silicone which will give 3 to 7 PPM in new oil. Silicone is used in "Print-O-Seal" cylinder head gaskets and crankshaft seals for engine which normally show 20 to 30 PPM silicone in the oil. Aluminum and cast iron parts in the engine can have significant amounts (up to 10%) of silicon in their composition.

Significant wear can be expected on the piston skirts and cylinder liners for this engine.

The engine is liquid-cooled; therefore, ethylene glycol present in the engine oil would indicate a leak in the coolant system.

Chromium (Cr)	Oil control piston ring faces are chrome plated.
Tin (Sn)	Plating on pistons.
Iron (Fe)	Wear of cylinder walls. Wear of numerous other engine parts. Also from machining chips left in engine.
Lead-Tin-Copper (Pb-Sn-Cu)	Crankshaft bearings, both mains and connecting rods. Wear of piston rings and crankshaft thrust washer.
Copper-Lead-Tin-Zinc (Cu-Pb-Sn-Zn)	Wear of many bushings.
Aluminum-Silicon-Cadmium (Al-Si-Cd)	Upper connecting rod bearing shell and No. 7 main bearing washer.

TECHNICAL INFORMATION

Engine oil is employed for cooling alternator.

Engine oil-wetted splines are used in accessory and reduction gearboxes (AGB and RGB).

Low levels (13 ppm) of zinc (Zn) may indicate use of galvanized containers for handling engine oil. This is harmless.

Over 75 ppm Zn with calcium (Ca), magnesium (Mg), or barium (Ba) present indicates transmission oil mixed with engine oil. Up to 10% transmission oil in engine oil can be tolerated indefinitely.

External sources should be considered first when attempting to explain Zn levels.

Iron (Fe) is by far the most important wear metal to monitor.

TECHNICAL INFORMATION

Silicone additives may be used for antifoaming agents in the lubricating oil, thus new oil normally gives a reading of 3 to 7 PPM silicon. Springs used in clutches for the transmission may have silicone coatings. This will result in high silicon readings on new or rebuilt equipment. Also, the transmission will normally show high iron readings during the break-in period.

The transmission is air-cooled; therefore, there should be no ethylene glycol contamination problems.

Abnormal Trend (PPM Increase in 10 hrs)	52	6	5	3	65	9	5		35		

TECHNICAL INFORMATION

When silver (Ag) and iron (Fe) are increasing excessively and at approximately the same rate, the silver-plated bushings (Part No. 7539858) in the steer differential pinion are wearing excessively. When silver (Ag) only is rapidly increasing, the silver-plated seal ring (Part No. 8352004) in the main oil pump may be wearing excessively, and the pump pressure should be monitored closely.

Some of the brake and clutch plates in the transmission are sintered bronze. When the iron and copper in the transmission are increasing at approximately the same rate, the plates may need adjustment, but are probably in good condition. On the other hand, if the iron wear rate exceeds the copper wear rate, the plates are probably worn excessively, and the transmission may fail. This is because the plates are worn through and the iron is coming from the backing plates. In a new transmission, the copper may run as high as 300 PPM with a much lower iron count until the transmission has worn-in and the fluid has been changed.

When the rear main oil seal in the AVDS 1790 engine wears excessively or ceases to function properly, there will be cross-contamination of the engine and transmission (CD-850-6A) lubricants. This, in general, will be indicated by increasing or high molybdenum (Mo) in the transmission oil samples and high copper and lead in the engine oil samples.

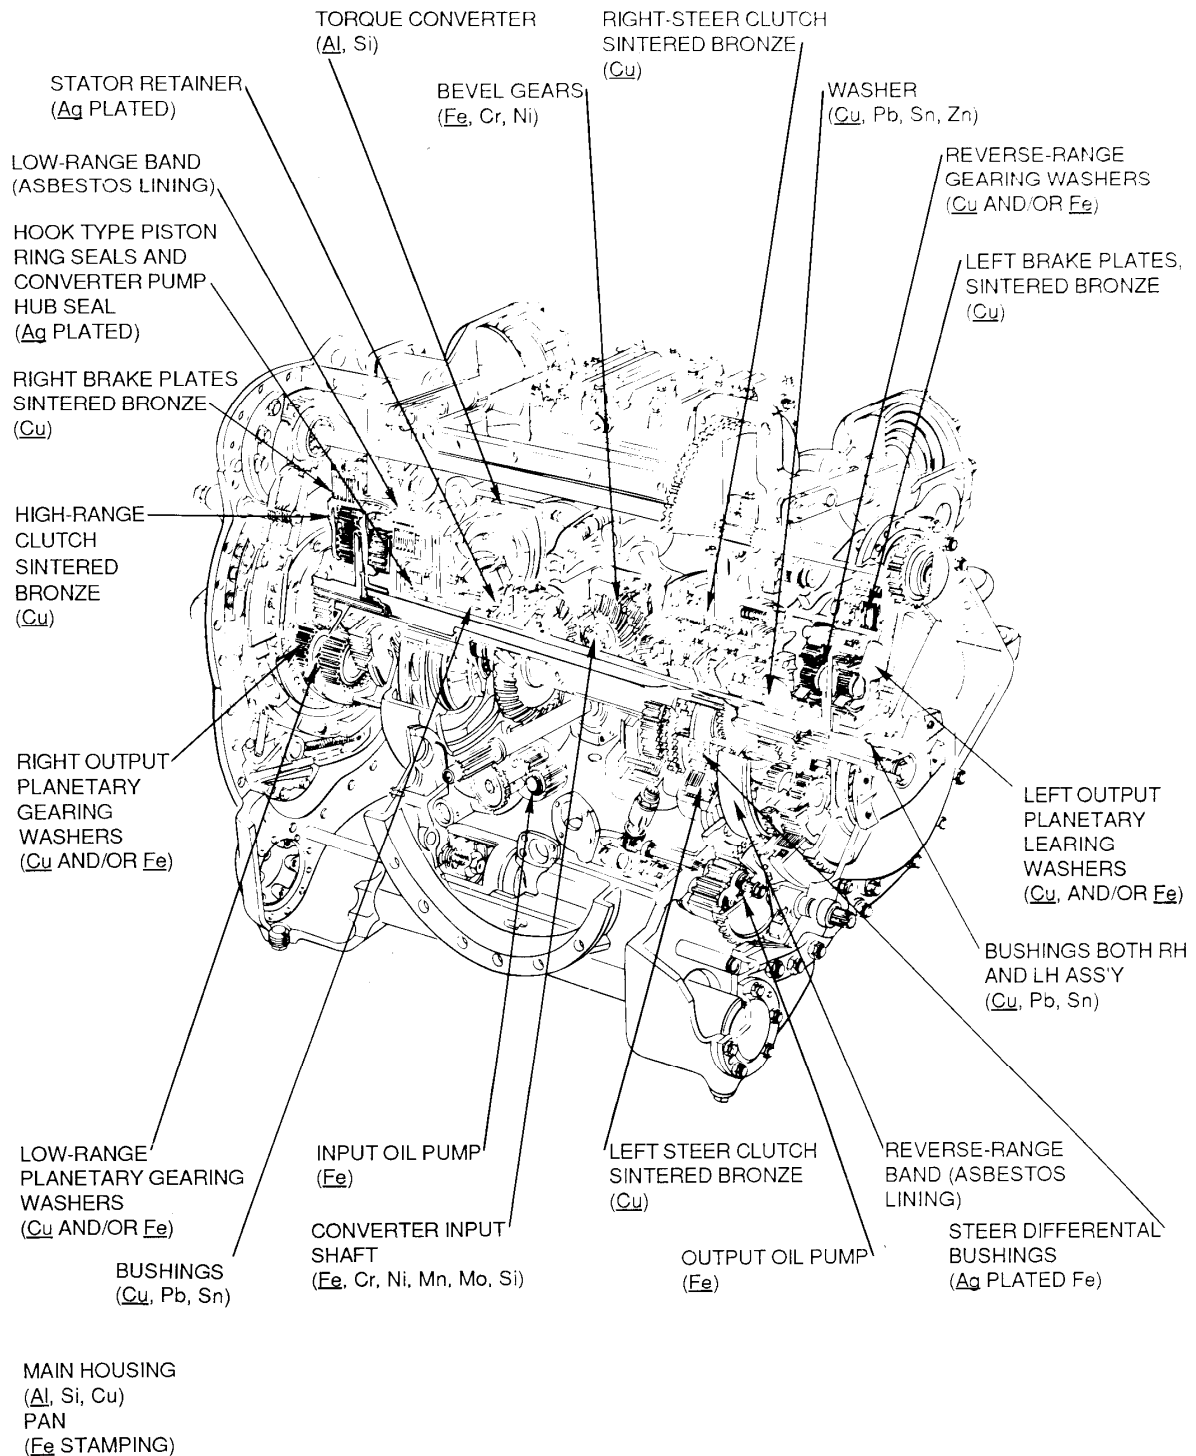

Transmission is air-cooled; therefore, no liquid-coolant contamination problems.

Wear of bushings is normally minimal.

Aluminum-Silicon (Al-Si)	Turbine converter, and first stator wear. Could also be derived from machining chips left in transmission. Aluminum particles are commonly found in pan.
Silicon (Si)	Aluminum and cast iron parts have significant amounts of silicon in their composition.
Silver (Ag)	Silver-plated oil seals and silver-plated planetary gear bushings.
Copper (Cu)	Brake and clutch plates contribute significant amounts of copper, especially in new or newly rebuilt transmission.
Copper-Lead-Tin (Cu-Pb-Sn)	Bushings.
Copper-Lead-Tin-Zinc (Cu-Pb-Sn-Zn)	Thrust washers.
Iron (Fe)	Wear of numerous transmission parts. Also machining chips left in transmission.

TECHNICAL INFORMATION

The brake and clutch plates in the transmission are sintered bronze. When the iron and copper in the transmission are increasing at approximately the same rate, the plates may need adjustment, but are probably in good condition. On the other hand, if the iron wear rate exceeds the copper wear rate, the plates are probably worn excessively, and the transmission may fail.

When aluminum or aluminum and iron are increasing excessively, wear is occurring in the transmission torque converter.

Increasing silver or silver and iron may be the result of wear of the plated hook-type seals.

TECHNICAL INFORMATION

Silicon additives may be used as antifoaming agents in the lubricating oil, thus new oil normally gives a reading of 3 to 7 PPM silicon.

Aluminum particles are commonly found in the transmission pan. Aluminum and cast iron parts have significant amounts of silicon in their composition.

Transmission is liquid-cooled; therefore, ethylene glycol may be present in the oil. If significant amounts of ethylene glycol are found, it is suggested that appropriate action be taken because the clutches and seals may be affected accordingly.

TECHNICAL INFORMATION

* The manufacturer states normal break-in is 5000mi/200hr/12mo, whichever is longest. During this time, an increase in Cu alone is not cause for concern. No action should be taken except to change oil when Cu reached 900 PPM. If Cu and another wear-metal element increase simultaneously, detrimental wear may be occurring and routine evaluation techniques apply.

Silicon additives may be used as antifoaming agents in the lubricating oil, thus new oil normally gives a reading of 3 to 7 PPM silicon.

Aluminum particles are commonly found in the transmission pan. Aluminum and cast iron parts have significant amounts of silicon in their composition.

Transmission is liquid-cooled; therefore, ethylene glycol may be present in the oil. If significant amounts of ethylene glycol are found, it is suggested that appropriate action be taken because the clutches and seals may be affected accordingly.

Transmission Wear Metal Baselines

These interim wear metal guidelines are based on the manufacturer's used lubrication oil chemical analysis. The Oil Analysis Standard Interservice System (OASIS) software will be modified to reflect actual wear metal parameters.

Wear Metal/ Coolant Elements		Normal Limits (PPM)\	Upper Limits (PPM)
Aluminum	(Al)	2 To 25	50 To 75
Boron	(B)	10 To 100	200 (See Notes)
Copper	(Cu)	20 To 150	300 To 400
Iron	(Fe)	10 To 100	200
Lead	(Pb)	5 To 50	150 or higher
Magnesium	(Mg)	0	-
Molybdenum	(Mo)	0	-
Silicon	(Si)	2 To 25	50
Sodium	(Na)	Less Than 25	-
Zinc	(Zn)	600 To 900	

NOTE: High readings of B, Mg, Mo, and Zn are usually indications of component's lubrication additive packages. If after establishing a base from obtaining a sample of the servicing oil, increases in the above mentioned elements are an indication of coolant/water contamination. If the component's oil sample is discolored, then recommend the transmission oil be changed.

Abnormal Trend (PPM Increase in 10 hrs)	63	6	50	3	78	6	10	3	65		

TECHNICAL INFORMATION

The brake and clutch plates in the transmission are sintered bronze. When the iron and copper in the transmission are increasing at approximately the same rate, the plates may need adjustment, but are probably worn excessively, and the transmission may fail. This is because the plates are worn through and the iron is coming from the backing plates.

The transmission is air-cooled; therefore, there should be no ethylene glycol contamination problems.

Probable sources of wear metals:

Fe - Steel gears

Ag - Hydrostatic cylinder cups

Al - Torque converter, oil pump, and main housing bearing

Cr and Mo - Steel alloys (usually < 4 PPM)

X1100-3B transmissions should not be removed or have the oil changed for silver (AG) wear metal test findings of 13 (PPM) or greater unless other abnormal wear metal indications are present.

When levels of silver of 13PPM or greater are indicated, without increases in other wear metals, AOAP labs will advise the equipment unit to conduct the following functional test in lieu of advising maintenance or servicing. The functional test is applicable **only** for indications of abnormal silver findings with no increase in other wear metals.

TQCOM, M1A2/SEP PM office in coordination with Allison, Inc. (OEM) recommended maintenance personnel conduct the following operational checks to determine transmission operational performance. Maintenance personnel should perform a functional test of the hydrostatic steering unit (HSU) on a hard or paved surface.

1. Select pivot steer, tac idle and perform a full 360° left steer turn, then return to a no-steer position in less than 20 seconds.
2. Next, perform a full 360° right steer turn and come back to a no-steer position in less than 20 seconds.
3. If the tank pivots in both directions (left and right) in less than 20 seconds (in each direction), the HSU is performing satisfactorily. However, if the tank fails to turn in either direction or fails to cycle within the specified time, perform this procedure again ensuring that the brakes are not partially applied. If it fails to meet the specified functional test operational requirements again, notify the appropriate maintenance personnel.
4. If the tank performs properly, no further action is required.

Until the current problem is resolved, report all X1100-3B transmission serial numbers with test findings where Ag 'only' exceeds the AOAP criteria to TACOM/PM M1A2/SEP Abrams Quality Assurance through PM AOAP.

Abnormal Trend (PPM Increase in 10 hrs)	82	15	5	3	203	6	10	3	54	4	

TECHNICAL INFORMATION

Increasing copper (Cu) usually indicates wear of clutch and brake plates. Rapid initial wear is normally experienced during "break-in" of new transmissions or newly installed clutch and brake plates. The clutch plates are in transmission center section assembly. Brake plates are in both the R.H. and L.H. output reduction (final drive) assemblies. These three assemblies have a common oil system; therefore, an oil analysis alone will not indicate where excessive wear has occurred. This can only be determined by careful observation and analysis of transmission and/or vehicle performance symptoms or inspections. For this same reason, whenever a failure has generated debris, the system including coolers, oil lines, transmission center section and both R.H. and L.H. output reduction assemblies must be thoroughly flushed or disassembled for cleaning.

When aluminum (Al) or aluminum and iron (Fe) are increasing excessively, wear is occurring in the transmission torque converter.

When silver (Ag) or silver and iron are increasing excessively, wear is probably occurring in the steer flywheel drive gear bushing or the thrust washers in the low, intermediate, reverse or output carriers. This may also indicate wear of the retainer progresses, aluminum may also increase. Increasing silver or silver and iron may also be the result of wear of the plated hook-type seal rings in the converter high clutch areas.

The transmission is air-cooled; therefore, there should be no liquid-coolant contamination problems.

Abnormal Trend (PPM Increase in 10 hrs)	56	4	69	1	8	229	2

TECHNICAL INFORMATION

The XT1410-5A transmission does not use engine oil MIL-L-2104; it uses Caterpillar Transmission/Drive Train oil meeting Caterpillar specification TO-4 (Cat TDTO, TO-4). This oil is specially formulated for transmissions and provides improved control of friction with the clutch, steering and brake plates. The most apparent benefit of using the Cat TDTO, TO-4 oil is the improved steering response.

Increasing copper (Cu) usually indicates wear of clutch, steering and brake plates. Rapid increases in Cu are normally experienced during initial break-in of new clutch, steering and brake plates in new or rebuilt transmissions and output reduction (final drive) assemblies.

The transmission center section assembly and the two output reduction (final drive) assemblies share a common oil system with continuous oil exchange. Therefore, an oil analysis alone cannot indicate which of the three assemblies is encountering excessive wear. This can only be determined by careful observation and analysis of transmission and/or vehicle performance symptoms or inspections. For this reason, whenever a failure has generated debris, the system, including oil coolers, oil lines, transmission center section and both right and left hand output reduction (final drive) assemblies must be thoroughly flushed or disassembled for cleaning.

When aluminum (Al) or aluminum and iron (Fe) are increasing excessively, wear is occurring in the transmission torque converter.

When silver (Ag) or silver and iron (Fe) are increasing excessively, wear is probably occurring in the steer flywheel drive gear bushing (in units prior to S/N BMY0282) or the thrust washers in the low, intermediate, reverse or output carriers. This may also indicate wear of the converter stator retainer washer. As wear of the retainer progresses, aluminum may also increase. Increasing silver or silver and iron may also be the result of wear of the silver-plated hook-type seal rings in the converter high clutch area.

The transmission oil is air-cooled. There should be no liquid coolant contamination problems.

TECHNICAL INFORMATION

This is 500-hp hydromechanical power transmission (HMPT) with fully automatic shifting, three forward and one reverse speed ranges.

It is liquid-cooled, but the transmission pressure is normally higher than the liquid-coolant pressure, therefore transmission oil would normally contaminate the coolant in the event of a common leak between the two.

Transmission has a tow pump to provide push- or pull-start capability for the vehicle engine.

Power take-off (PTO) could present wear and oil contamination problems.

Notes

The prevalent metal/elemental components in these transmissions are comprised of Aluminum (Al), Iron (Fe), Copper (Cu), Tin (Sn) and Lead (Pb). Typical contamination elements are Silicon (Si) from dirt and additive, and Sodium (Na) representing salt from the dirt. MIL-PRF-2104 products are used in the transmissions.

The Titanium (Ti), Chromium (Cr), and Nickel (Ni), are not considered adequate for use as wear metals since there are no components with those elements in any concentration that should be monitored. Therefore, it is recommended that these elements should not be monitored under AOAP for the M1070, M1074, and M1075 transmissions.

Zinc (Zn), Molybdenum (Mo), Boron (B), and Magnesium (Mg) are typical additives found in products under MIL-PRF-2104. Mg can also be found in some metallic alloys. However, when the Mg is an additive it can be found in concentrations as high as 600 ppm. Therefore, Mg is not a good indicator of wear since there is no way to determine how much is from the additives and how much is from wear. Unlike Zn, not all lubricant products contain B, Mg, or Mo. B and Mo, like Mg, are not recommended for use as elements to be used for condition since they are not wear elements nor a typical value can be determined for oil condition. The element Zn is an exclusive result of additives. The range of values for Zn in oil is 1000-1300 ppm. This range is a normal range for Zn. Values lower than 900 ppm should be considered suspicious since it would be a result of a non-MIL-PRF-2104 product.

COMPONENT: THM-400/THM-4L80E Transmission Wear Metal Baselines

These interim wear metal guidelines are based on the manufacturer's used lubrication oil chemical analysis. The Oil Analysis Standard Interservice System (OASIS) software will be modified to reflect actual wear metal parameters.

Wear-metal/Coolant Elements

	Al	B	Cu	Fe	Pb	Mg	Mo	Si	Na	Zn
Normal	2-25	10-100	20-150	10-100	5-50	0	0	2-25	<25	600-900
Upper Limits	50-75	200*	300-400	200	150+			50		

*See notes

NOTE: High readings of B, Mg, Mo, and Zn are usually indications of component's lubrication additive packages. If after establishing a base from obtaining a sample of the servicing oil, increases in the above mentioned elements are an indication of coolant/water contamination. If the component's oil sample is discolored, then recommend the transmission oil be changed.

TECHNICAL INFORMATION

NOTES

General information on the metallurgy of the hydraulic system indicates the metals found in hydraulic systems are Iron (Fe), Aluminum (Al), Magnesium (Mg), and Copper (Cu).

MIL-PRF-2104 fluid is used for all listed components except for the M1000, which requires a hydraulic fluid.

Additives found in products under MIL-PRF-2104 can contain the following elements: Zn, Mg, Mo, Si, Ca, and B (Ca is not currently included in the AOAP and is only mentioned as reference). The concentrations can vary depending on the technology used. Only the element Zn is found all the time at concentrations between 1000-1300 ppm. Si is found between 5-20 ppm. The other elements can range from 0-600 ppm.

The following elements are not recommended to be monitored/used to determine condition of the system: Ag, Cr, Ni, Sn, Ti, Pb, B, Mo, and Zn are either not part of the metallurgy of the system (at least in any significance) or the oil contributions would overshadow any wear limits making monitoring worthless. The problem with elements that are in the oil is that they can change in concentration from 0 to the maximum range indicated above and therefore significantly affect AOAP limits.

TECHNICAL INFORMATION

Increasing silicon (Si) usually indicates contamination of the servicing component oil system. A drain and flush of the hydraulic system, including replacement of both the return circuit filter and the charge circuit filter, will reduce abnormal silicon analysis readings.

The presence of iron (Fe) or iron and water (H₂O) is probably rust occurring as a result of condensation or internal oil pump and/or component wear; such as cooler, quick disconnect valves, cross overlines, etc., since this is a closed operating system. Components would include the cooler, quick disconnect valves, cross-over lines, etc. Analysis readings of 1,000 parts per million (PPM) or more of water in a hydraulic oil sample usually warrants a recommendation to change oil and service or replace the filter. The FT-IR test for the presence of water in EP additive fluids is observed as a baseline rise or offset, but does not show the evidence of Tyndal-particulate or colloidal scattering.

APPENDIX C

NAVY (SHIPS) PHYSICAL PROPERTY TEST LIMITS BY TYPE OIL AND USE

Physical test procedures are contained in Volume II.

USED AS A DIESEL LUBE OIL

MIL-L-9000G MS-9250

Spectrometric Required

<u>Test</u>	<u>Limits</u>
Water (by Crackle)	0.2% Max.
Viscosity (at 100° F) report in Centistokes (CS)	100 CS Min. 225 CS Max. Warning if Visc increases 40% or decreases 10% from sample.
Acidity	Blue = Pass, Green or Yellow = Fail
Fuel Dilution: Always perform when Viscosity is less than 130 CS, at 100° F, or odor of fuel is present.	Greater than or equal to 2% but less than 5%, notify customer of fuel contamination 5.0% Abnormal: Change oil. Inspect for fuel leak.

USED AS LUBE OIL

MIL-L-17331 MS-2190 TEP

Spectrometric Required

<u>Test</u>	<u>Limits</u>
Water	Crackle – 0.10 percent
Neutralization Number	0.5 Max

GAS TURBINE LUBE OIL

MIL-L-23699

Spectrometric Required

<u>Test</u>	<u>Limits</u>
Viscosity (at 100° F) report in Centistokes (CS)	25 CS Min. 37 CS Max.
Neutralization Number	1.5 Max.

REFRIGERANT COMPRESSOR OIL

**VV-L-825+
MS RCO-2 (TYPE II); MS RCO-4 (TYPE IV)**

Spectrometric Required

<u>Test</u>	<u>Limit</u>
Water	0.01% / 100 PPM Max.
Neutralization Number	0.1 Max

USED AS LUBE OIL

**MIL-L-15019
MS 6135**

Spectrometric Required

<u>Test</u>	<u>Limits</u>
Neutralization Number	1.25 Max.
Water	0.2% Max.

 EQUIPMENT MODEL: Hardy Tynes

	Fe	Ag	Al	Cr	Cu	Mg	Pb	Sn	Ni	Si	
Normal Range	0-2	0-2	0-2	0-2	0-5	0-22	0-11	0-2	0-2	0-11	
Marginal Range	3-5	3-5	3-5	3-5	6-13	23-52	12-29	3-5	3-5	12-29	
High Range	6-10	6-10	6-10	6-10	14-20	53-64	30-40	6-10	6-10	30-40	
Abnormal	11+	11+	11+	11+	21+	65+	41+	11+	11+	41+	
Abnormal Trend (PPM Increase in 10 hrs)											

Average Concentration Other Elements:

NAVAIR 17-15-50.4
TM 38-301-4
T.O. 33-1-37-4
CGTO 33-1-37-4

TYPE EQUIPMENT: Air Supply System
SYSTEM/USE: Forced Draft Blower
EQUIPMENT MODEL: Westinghouse
